# PRIVATE INFORMATION RETRIEVAL: PRACTICAL PIR

# FOR REAL DATABASES

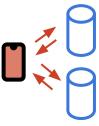

WIP at PETS
Sofía Celi

cherenkov@riseup.net

A Private Information Retrieval (PIR) scheme provides the ability for clients to retrieve items from an online public (\*) database of *m elements*, without revealing anything about their queries to the untrusted host server(s)

- Parties:
  - a. Client(s)
  - b. Server (one or multiple)
- Steps:
  - Query
  - Response
  - Parse

#### Two types (sort of):

- Information-theoretic PIR: client interacting with multiple non-colluding servers
- 2. **Computational-theoretic PIR**: client interacting with a single server, provides computational security based on cryptographic assumptions:
  - a. Stateless PIR:
    - The client does not store any (pre)information in order to launch queries
    - The schemes (a bunch!) perform worse than downloading the whole DB or they require computational overheads

#### Two types (sort of):

- Information-theoretic PIR: client interacting with multiple non-colluding servers
- 2. **Computational-theoretic PIR**: client interacting with a single server, provides computational security based on cryptographic assumptions:
  - a. Stateless PIR
  - b. **Stateful PIR:** provides a "state" (or hint/digest) used as a "preprocessing" step amortised over *n* client queries

#### Two types (sort of):

- Information-theoretic PIR: client interacting with multiple non-colluding servers
- 2. **Computational-theoretic PIR**: client interacting with a single server, provides computational security based on cryptographic assumptions:
  - a. Stateless PIR
  - b. Stateful PIR

Idea: encrypt the query instead of secret-sharing it

#### Limitations in **Computational-theoretic PIR**:

- Expensive pre-processing in terms of computation or communication
- High online-phase bandwidth consumption
- Lack of practical security parameters
- Lack of simple, open-source, available, verified implementations

#### **Current look**

Very active research area

Promising efficiency (computational/communicational/financial)

Variety of applications

# Which applications?

Some deployments / related technologies exist:

Brave (compromised credential-checking, TBD)
Blyss (https://github.com/blyssprivacy/sdk)
Google (Device Enrollment)
Microsoft (Password Monitor)

More complex use-cases (not deployed):
Approximate nearest-neighbor: Brave News
Private search: TipToe
Oblivious document ranking: Coeus

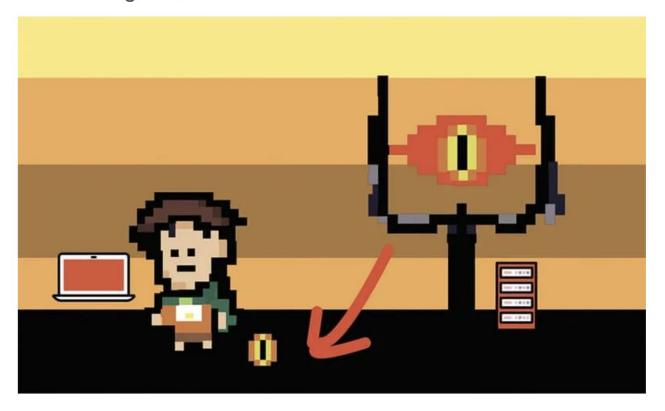

# **FRODOPIR**

(but also *SimplePIR*)

https://eprint.iacr.org/2022/981

https://eprint.iacr.org/2022/949

#### Announcing FrodoPIR!

Just as the state of Sauron (its ring) moved to Frodo, we can move the mu and A to the client.

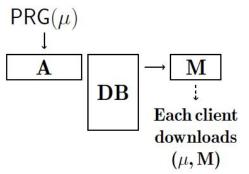

The client then can then perform hidden queries to the server, just as Frodo remains hidden from Sauron.

#### **Core ideas**

- Built directly upon the learning with errors (LWE) problem *only* (similar to FrodoKEM)
  - Security relies on decisional LWE
  - Security is conservative (128 bits for 2^52 client queries): some parameters can be modified in order to make the scheme more efficient
- Highly configurable
  - Differences with SimplePIR: different pre-processing encoding, and the addition of a query pre-processing stage
- Tailored for efficiency and real-world applications

(1) Server Offline Pre-processing (2) Client Offline Pre-processing

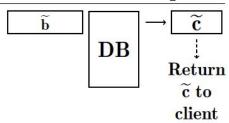

$$\mathbf{b} = \mathbf{S} \mathbf{A} + \mathbf{e}$$

$$\{0, \pm 1\} \text{ PRG}(\mu) \quad \{0, \pm 1\} \quad \$\downarrow$$

$$\mathbf{b} = \mathbf{S} \mathbf{A} + \mathbf{e}$$

(3) Client Online Query for Index i (4) Server Online Response

$$\boxed{\mathbf{b} + \begin{bmatrix} 0 \\ \overline{X} \\ 0 \end{bmatrix}}_{\mathbf{i}} \longrightarrow \begin{bmatrix} \widetilde{\mathbf{b}} \\ \cdots \end{bmatrix} \xrightarrow{\mathbf{Send}} \mathbf{to}$$
 server

(5) Client Output

$$\mathbf{Round} \boxed{\widetilde{\mathbf{c}}} - \boxed{\mathbf{c}} \approx \boxed{\mathbf{DB}[i]}$$

#### **Notation**

- DB is an array of m elements, each made up of w bits.
- Each entry is associated with the index *i* that corresponds to its position in the array.
- There are *C* clients that will each launch a maximum of *c* queries against DB.
- LWE:
  - a. n and q are the LWE dimension and modulus, respectively
  - b.  $\rho$  is the number of bits packed into each entry of the DB matrix (0 <  $\rho$  < q)
  - c.  $\chi$  is the uniform ternary distribution over {-1, 0, 1}
  - d.  $\lambda$  is the concrete security parameter.
- PRG(μ, n, m, q) denotes a pseudorandom generator that expands a seed

$$\mu \in \{0,1\}^{\lambda} \in \mathbb{Z}_q^{x \times y}$$

# FrodoPIR (offline: server)

- **Server setup**: The server constructs their database containing m elements, and samples a seed  $\mu \in \{0,1\}^{\lambda}$
- **Server pre-processing:** The server:
  - Derives a matrix  $A \leftarrow PRG(\mu, n, m, q)$
  - Runs  $D \leftarrow parse(DB, \rho)$
  - Runs  $M \leftarrow A \cdot D$
  - Publishes the pair  $(\mu, \mathbf{M}) \in \{0, 1\}^{\lambda} \times \mathbb{Z}_q^{n \times \omega}$

The "hint" is 
$$M \leftarrow A \cdot D$$

$$\mathbf{A} \in \mathbb{Z}_q^{n \times m}$$

$$\mathbf{D} \in \mathbb{Z}_q^{n \times \omega}$$

$$\omega = w/\log(\rho)$$

## FrodoPIR (offline: client)

#### **Pre-processing.** Each client:

- Downloads  $(\mu, \mathbf{M})$
- Derives  $A \leftarrow PRG(\mu, n, m, q)$
- Samples c vectors:  $j \in [c]$ -  $s_j \leftarrow \chi^n \quad e_j \leftarrow \chi^m$

- Computes:

$$b_{j} \leftarrow s_{j}^{T} \cdot \mathbf{A} + e_{j}^{T} \qquad \in \mathbb{Z}_{q}^{m}$$

$$c_{j} \leftarrow s_{j}^{T} \cdot \mathbf{M} \qquad \in \mathbb{Z}_{q}^{\omega}$$

- Stores the pairs as the set  $X = (b_j, c_j)_{j \in [c]}$ 

Essentially, computes c sets of preprocessed query parameters (optional step).

## FrodoPIR (online: client)

**Query generation.** For the index *i* that the client wishes to query, the client generates a vector (the all-zero vector except where  $f_i[i] = q/\rho$ ):

$$f_i = (0, \cdots, 0, q/\rho, 0, \cdots, 0)$$

It then pops a pair (b, c) from internal state and computes:

$$b' = b + f_i$$

The client uses a single set of preprocessed query parameters to produce an "encrypted" query vector, which is sent to the server

# **FrodoPIR (online: server)**

**Response.** The server receives *b'* from the client, and responds with:

$$c' \leftarrow b' \cdot \mathbf{D}$$

$$\in \mathbb{Z}_q^{\omega}$$

Essentially, the server responds by multiplying the vector with their DB matrix

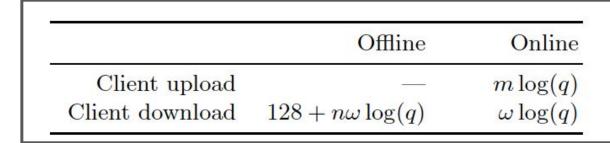

**Post-processing.** The client receives *c'*, and calculates:

$$v \leftarrow \lfloor (c'-c)_{\rho} \rceil$$

Essentially, the client gets the value by "decrypting"

# **FrodoPIR Properties**

#### Efficiency.

$$128 + n\omega \log(q) + c\omega \log(q) < |DB|.$$

Holds for large *c*: c > 18000 for  $m = 2^{16}$

# **FrodoPIR Properties**

**Security:** Indistinguishability of client queries. It assumes a semi-honest server that follows the protocol correctly and attempts to learn more based on the client queries they receive:

Server view: b' is distributed uniformly in  $\mathbb{Z}_q^m$ 

under the assumption that decional-LWE is difficult to solve

 Regev encryption remains secure even when the same matrix A is used to encrypt many messages, provided that each ciphertext uses an independent secret vector s and error vector e

Chris Peikert, Vinod Vaikuntanathan, and Brent Waters. *A framework for efficient and composable oblivious transfer*.

## **FrodoPIR Properties**

**Security:** Indistinguishability of client queries.

We use the *decisional Matrix LWE problem*: extended form of the problem in which the secrets and errors are also matrices to prove *l-query indistinguishability* (with  $l = poly(\lambda)$ )

 A standard hybrid argument shows that any adversary that can distinguish the two distributions with advantage ε can be used to construct an efficient adversary breaking the decision LWE problem with advantage at least ε/l

J. W. Bos, C. Costello, L. Ducas, I. Mironov, M. Naehrig, V. Nikolaenko, A. Raghunathan, and D. Stebila. *Frodo: Take the ring! Practical, quantum-secure key exchange from LWE*.

 $\kappa = (log(p) * m) / (n * log(q))$  denote the improvement factor relative to the offline client download, compared to the DB size.

128 bits of security for  $2^{52}$  queries: security can increase by increasing the dimension but this will impact  $\kappa$ 

q	$2^{32}$	$2^{32}$	$2^{32}$	$2^{32}$	$2^{32}$
n	1774	1774	1774	1774	1774
m	$2^{16}$	$2^{17}$	$2^{18}$	$2^{19}$	$2^{20}$
ρ	210	210	$2^{10}$	$2^9$	$2^9$
κ	13.028	26.056	52.112	93.802	187.603
λ	128	128	128	128	128

# How we come up with it?

- Based on Regev's encryption where the expansion factor is roughly  $F = n \approx 1024$ , where n is the lattice security parameter
  - Do a lot of the work in advance and re-use
  - Additively homomorphic

$$(a,c) = (a, a^T s + e + \lfloor q/\rho \rfloor \cdot \mu) \in \mathbb{Z}_q \times \mathbb{Z}_q$$

- We use a ternary uniform distribution (bounded by  $4\sqrt{m}$ , with m being the number of samples taken from the distribution)
- Z. Brakerski, A. Langlois, C. Peikert, O. Regev, and D. Stehle. *Classical hardness of learning with errors*.

# What are the advantages?

- 1. It is simple: easy to explain, easy to push to production
- 2. LWE-based PIR schemes are simple to implement: they require no polynomial arithmetic or fast Fourier transforms
- 3. LWE-based PIR schemes do not require the server to store any extra per-client state. In contrast, many schemes based on Ring LWE rely on optimizations that require the server to store one "key-switching hint" for each client
- 4. LWE-based PIR schemes are faster and cheaper: the encryption scheme needs to be linearly (not fully) homomorphic, so we can use smaller and more efficient lattice parameters

# But, is this enough?

- Databases are not structured in this simple way
  - They are indexed by keywords
  - They are structured as JSON, Graphs, Excel spreadsheets
- The queries we are interested in are not simple:
  - Complex queries with AND/OR statements
  - Combination of database systems
  - Approximate nearest neighbor (ANN) elements
- Databases are constantly updated
- Is the security we assume enough?
  - What about malicious security?
  - What about private databases?

Not all systems are created equally

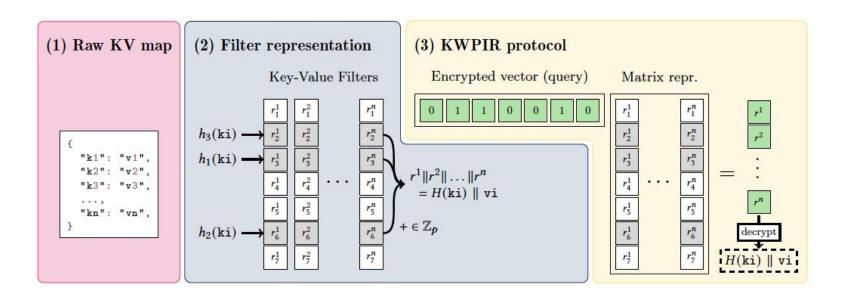

# **CHALAMET-PIR**

(one solution)

https://eprint.iacr.org/2024/092

#### **Core ideas**

• Very simple (®) idea

#### **Core ideas**

- 1. Have a DB structured as a Key-Value (KV) map (size *m*, where each element *v* is indexed by a key *k*)
- 2. Convert this map into a filter (*F*) structure (think on a Bloom Filter) with a set of *k* hash functions and some false positive probability
  - a. The filter has a function that allows to recover  $v: fpt_{\epsilon}(v) \leftarrow F.check(k)$
  - b. The filter is broken into d columns: interpret it as a matrix with cm (\*) rows
- 3. Query for an element with a long vector where there are 1s on  $h_i(k)$

<sup>(\*)</sup>  $1.08 \le \varsigma \le 1.13$ , depending on the choice of  $k = \{3, 4\}$ 

#### **Basic construction**

- Same ideas as previous in literature, but:
  - We leverage the usage of Binary Fuse Filters
    - Minimise the space and query overheads of key-value filters, while maintaining quick access times
    - Reconstruct using XOR
    - Divide the filter into many more segments
  - We can use any LWE-based PIR scheme

# **Properties**

- Security: Same as FrodoPIR (LWE-based), but:
  - We allow for false-positives, as we assume a public database. What impact does this have?
  - We provide a random value in case of non-inclusion -> leakage impact
- **Efficiency:** Same as FrodoPIR (LWE-based), but:
  - Blow-up due to filter: ç

- Is it sufficient?
  - Assumes the same length of elements

# WHAT ELSE?

# **Upcoming solutions**

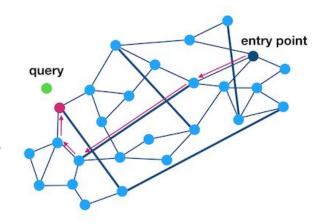

- PIR for k-ANN
  - Real applications to search engines and recommendation systems
  - State-of-the-art k-ANN algorithms
- Integrate new security properties:
  - Expand to symmetric model
  - Expand to malicious security
- Deal with complex queries and complex databases
  - Not all databases are created equally:
    - Brave News
    - Brave Search
    - Brave CT

# **Upcoming solutions**

- PIR for k-ANN
  - Real applications to search engines and recommendation systems
  - Graph-like structure that can be represented as a matrix
    - Dig into graph/matrix techniques to spectrally reason about them
  - State-of-the-art k-ANN algorithms

#### Future paper soon!, but:

How to deal with updates in a graph/matrix structure?

# **Upcoming solutions**

- PIR for k-ANN
- Integrate new security properties:
  - Expand to symmetric model
  - Expand to malicious security
- Deal with complex queries and complex databases
  - Not all databases are created equally:
    - Brave News
    - Brave Search
    - Brave CT
- A simple but needed SoK

# My (sad) take

- We are very behind real databases-systems
- We are very behind state-of-the-art data structure/graph's research
  - Why haven't we look beyond Cuckoo filters and Merkle Trees?
- We are very behind actual deployment

But we are making progress!

# **Building steps**

#### Ideas

- Expand the security model:
  - How does leakage impact it?
  - Is it attackable?
- Introduce 'updatable' techniques
- Look at other applications of DB:
  - o Do we fulfil them?
- How do we deal with variable-length elements?
  - Is padding enough?
- Can we make it simple with the ring?
- Can we look at state-of-the-art data structures/graphs/matrix theory?

Thank you Henry Corrigan-Gibbs, Alex Davidson, Alexandra Henzinger, Stefano Tessaro, Eli Richarson for input and discussing all of this!

# **THANK YOU!**
